CLINICAL PEARL

- The clinical presentation, laboratory and radiologic findings of children with COVID-19 differ from those of adults: A US report of 291 children with confirmed COVID-19 found that the most common symptoms were fever (56%) and cough (54%). Nearly one-third of children had gastrointestinal complaints of abdominal pain, nausea/vomiting, and diarrhea. Other non-specific symptoms included rhinorrhea, sore throat, headache, and myalgia. These figures vary greatly from adults in the same report, in whom fever and cough were reported in 71% and 80% of patients, respectively.
- While adults with COVID-19 tend to have an elevated white blood cell count and elevated inflammatory markers, several studies have found that the majority of children have a normal or low white blood cell count, and normal inflammatory markers, including normal C-reactive protein, procalcitonin, and ferritin levels. This reflects the lack of immune dysregulation that is more commonly seen in adults and may provide an explanation for why children with COVID-19 tend to have milder symptoms, if any. An exception is the MIS-C presentation likely due to a dysregulated inflammatory response, which is characterized by significantly elevated inflammatory markers.
- In cases of severe disease requiring hospital admission, computed tomography (CT) of the chest may prove useful. The most common CT findings in the pediatric population include unilateral and bilateral subpleural ground-glass opacities and consolidation with a surrounding halo sign. The halo sign is not routinely seen in CT images from adult patients and is suggested to be a “characteristic finding” in affected children. Many also advocate the use of lung ultrasound, especially given that it is radiation-free and portable, thereby limiting patient transport within the hospital and minimizing exposure to other patients and staff. Lung ultrasound findings in children include subpleural consolidations and interstitial B lines. Improvements in these parameters are often seen on repeat ultrasound prior to discharge, suggesting that serial ultrasounds could be used in the pediatric population to monitor disease activity, treatment response and to assess recovery.
