CLINICAL PEARL

- SARS-CoV-2 variant with multiple spike protein mutations: Since November 2020, a variant strain of SARS-CoV-2 has become prevalent in the southeast of England, reportedly accounting for 60% of recent infections in London. This variant has a mutation in the receptor binding domain (RBD) of the spike protein at position 501, where amino acid asparagine (N) has been replaced with tyrosine (Y). The shorthand for this mutation is N501Y, sometimes noted as S:N501Y to specify that it is in the spike protein. This variant carries many other mutations, including a double deletion (positions 69 and 70). Prior work on variants with N501Y suggests they may bind more tightly to the human angiotensin-converting enzyme 2 (ACE2) receptor. At present, the variant is referred to as “SARS-CoV-2 VOC 202012/01” (i.e., the first variant of concern from 2020, December), or “B.1.1.7.” VOC 202012/01 so far has no known association with animals or animal contact.

While it is known and expected that viruses constantly change through mutation leading to the emergence of new variants, preliminary analysis in the United Kingdom (UK) suggests that this variant is significantly more transmissible than previously circulating variants, with an estimated potential to increase the reproductive number (R0) by 0.4 or greater, and with an estimated increased transmissibility of up to 70%. There is no indication at this point of increased infection severity or increased risk of death associated with the new variant.

To date, the VOC 202012/01 variant has not been identified in San Mateo County. It was recently identified in Colorado and in San Diego. Given the small fraction of US infections that has been sequenced to date (about 51,000 of the 17 million US cases), it is likely that the variant has been in the United States for a while without having been detected. The variant has been detected in multiple European countries, as well as Canada, the Middle East, Southeast Asia and Oceania. On December 18, 2020, the South African government announced that it had also seen the emergence of a new strain in a scenario similar to that in the UK. The South African variant also has the N501Y mutation and several other mutations but emerged completely independently of the UK strain and is not related to it.
