## Airway: Foreign Body Removal

## **Clinical Indications:**

 Sudden onset of respiratory distress often with coughing, wheezing, gagging, P or stridor due to a foreign-body obstruction of the upper airway.

## **Procedure:**

- 1. Assess the degree of foreign body obstruction.
  - a. Do not interfere with a mild obstruction; allow the patient to clear their airway by coughing.
  - b. In severe foreign-body obstructions, the patient may not be able to make a sound. The patient may clutch his/her neck demonstrating the universal choking sign.
- 2. For an infant, deliver 5 back blows (slaps) followed by 5 chest thrusts (compressions) repeatedly until the object is expelled or the patient becomes unresponsive.
- 3. For a child, perform a subdiaphragmatic abdominal thrust (Heimlich Maneuver) until the object is expelled or the patient becomes unresponsive.
- 4. For adults, a combination of maneuvers may be required.
  - a. First, subdiaphragmatic abdominal thrusts (Heimlich Maneuver) should be used in rapid sequence until the obstruction is relieved or the patient becomes unresponsive.
  - b. If abdominal thrusts are ineffective, chest thrusts should be used. Chest thrusts should be used primarily in morbidly obese patients and in patients who are in the late stages of pregnancy.
- 5. If the patient becomes unresponsive, begin CPR immediately but look in the mouth before administering any ventilations. If a foreign-body is visible, remove it.
- 6. Do not perform blind finger sweeps in the mouth and posterior pharynx. This may push the object farther into the airway.
- 7. In unresponsive patients, Paramedics should visualize the posterior pharynx with a laryngoscope to potentially identify and remove the foreign-body using Magill forceps.
- 8. Document the methods used and result of these procedures in the EHR.
