Intraosseous Access

Applies to:

P

Paramedic

Clinical Indications:

- 1. Patients where rapid, regular IV access is unavailable with any of the following:
 - Cardiac arrest
 - b. When IV access is unsuccessful or, after evaluation of potential sites, it is determined that an IV attempt would not be successful in the setting of:
 - i. Shock or evolving shock, regardless of the cause.
 - ii. Impending arrest or unstable dysrhythmia.

Contraindications:

- 1. Fracture of the targeted bone.
- 2. IO within the past 48 hours in the targeted bone.
- 3. Infection at the insertion site.
- 4. Burns that disrupt actual bone integrity at the insertion site.
- 5. Inability to locate landmarks or excessive tissue over the insertion site.
- 6. Previous orthopedic procedure near the insertion site (e.g., prosthetic limb or joint).

Procedure:

- 1. Proximal humerus (preferred site in adults only, if available)
- 2. Proximal tibia
- 3. Distal tibia (if proximal humerus or proximal tibia are unsuitable)

Procedure:

- 1. Locate the insertion site:
 - a. The proximal humerus site is the greater tubercle, identifiable as a prominence on the humerus when the arm is rotated inward and the patient's hand is on the abdomen.
 - b. The proximal tibia site is on the flat medial aspect of the tibia, 2 finger-breadths below the lower edge of the patella and medial to the tibial tuberosity.
 - c. The distal tibia site is 2 finger-breadths above the most prominent aspect of the medial malleolus (inside aspect of ankle) in the midline of the shaft of the tibia.
- 2. Prep the selected site with alcohol and allow to air dry.

Intraosseous Access

- 3. Select and load the appropriate sized needle on the driver.
 - a. For humeral access, a 45mm (yellow) needle is used except in patient adults less than 40kg.
 - b. For proximal and distal tibial access, the amount of soft tissue should be gauged to determine if a 25mm (blue) or 45mm (yellow) needle is appropriate.
- 4. Introduce the IO needle through the skin without engaging the power driver:
 - a. For humeral access, the direction of the needle should be perpendicular to the skin, directed at a downward angle of 45 degrees from the frontal plane, heading slightly downward toward the feet.
 - b. For tibial sites, the direction of the needle should be at a 90 degree angle to the flat surfaces of the tibia.
- 5. Once the needle has touched the bone surface, assess to see if the black line on the needle is visible. If it is not visible, either a larger needle is needed, or in the case of the 45mm needle, the soft tissue is too thick to allow the use of that needle.
- 6. With firm pressure, insert needle using the power driver.

 In most cases, the hub should be flush or touching the skin in adults; stop at the loss of resistance in peds. Verify that the needle is firmly seated in the bone; it should not wobble.
- 7. Remove the stylet and introduce Lidocaine if the patient is not in arrest.
 - a. For conscious adult patients, 40mg of Lidocaine should be infused slowly over 1-2 minutes and allow 1 additional minute before flushing.
 - b. For patients in arrest, Lidocaine is not necessary but may be needed if the patient regains consciousness.
- 8. Stabilize device to skin.
- 9. Flush with 10ml Saline. In conscious patients, flush with 5ml Saline initially and repeat if necessary.
- 10. Attach IV tubing to IO hub and begin infusion using pressure bag.
- 11. If painful, an additional 20mg of Lidocaine can be infused over 30 seconds, and after another minute, infusion should be restarted.
- 12. Monitor site for swelling or signs of infiltration and monitor pulses distal to area of placement.
- 13. Place wristband included with IO set on patient and document time of insertion on wristband.
